

Global Crop Yields

This dashboard shows the value and food energy each country gets from its farmland, and how these have changed over time. Most figures use US dollars, not tonnes. A dollar of any crop is comparable; a tonne of one crop is not equal to a tonne of another. All figures come from FAOSTAT and World Bank data. No figure is invented or entered by hand.

FAO/World Bank data, 2005–2022. Since 2012, a fixed group of historically top-yielding countries has pulled further ahead of the global median (+22.8% vs +11.2%).

Year

2022

Global Value 2022

14 of the countries shown are estimated (World Bank proxy, not FAOSTAT). Hover a country to see which.

This map shows each country's total crop production value per hectare of arable land.

This is a country total, not a per-crop figure. It does not change with which crops a country happens to report in a given year.

FAOSTAT has no item-level Value of Production data for the EU after 2017. This map uses each EU country's total value instead, which FAOSTAT still reports.

Hover a country to see whether its value is FAOSTAT-reported or estimated. FAOSTAT has no Value of Production figure for 14 of the countries shown. Their estimate uses World Bank agricultural value-added data instead, a related but different measure. 6 of these are conflict-affected countries; their estimate carries extra uncertainty, noted in the hover text. The \$ vs kcal map below shows the same countries. Only the Top Value and Value per Arable Hectare rankings exclude them, since those rank FAOSTAT-reported figures only.

The color scale is logarithmic. Value per hectare is heavily skewed: a few countries are far above the rest.

Top Crops by Value, 2022

This chart ranks the top 10 crops by total value, summed across countries with item-level data.

This is not the same ranking as by tonnage. Tea alone reaches this list on price: its tonnage is a small fraction of wheat's or rice's.

EU countries are undercounted here since 2018. See Notes below for the per-crop reporting gap this chart shares with Crop Value vs. Cultivated Area.

Crop Value vs. Cultivated Area, 2022

Value per Arable Hectare 2022

050M100M150M200M

Cultivated Area (ha)

Each bubble is one crop. It plots total value against total cultivated area, across all reporting countries.

Bubblesize shows the number of countries growingthat crop with item-level value data.

This chart shares thesameEU per-crop gap as Top Crops byValue above. SeeNotes below.

05k10k15k20k

Value / arable ha (USD)

This chart ranks the top 10 countries by value per arable hectare.

Arableland excludes permanent-crop land such as palm oil, bananas, and coffee. This favors tree-crop economies.

This chart excludes countries with under 100,000 ha of arable land. SeeTop Valueabove for why.

\$ vs kcal per Arable Hectare 2022

Teal → kcal-oriented | Red → ROI-oriented

kcal-orientedbalancedROI-oriented

14 of the countries shown are estimated (World Bank/FAOSTAT proxy). Hover a country to see which.

Teal countries lean toward feeding people. Red countries lean toward export or cash value.

Both sides come from FAOSTAT's own figures. Value comes from Gross Production Value; food energy comes from Food Balance Sheets. Value data covers about 64% of tracked items and excludes coffee, onions, and most tree nuts. For the EU after 2017, this map uses FAOSTAT's aggregate categories instead of item-level data.

Food energy excludes crops that mostly become a separately-tracked product: barley, cotton seed, oil palm fruit, rape or colza seed, soya beans, sugar beet, sugar cane, sunflower seed. These crops keep their full value on the dollar side, with nothing removed to match. Countries dominated by these crops (Malaysia, Mauritius, Barbados, Cabo Verde) skew toward red here. This is a data artifact, not always a real choice.

This map drops countries using under 5% of their nominal arable land for tracked crops. Below this level, a small numerator becomes an extreme data point. Iceland is the clearest case: only about 3% of its arable-land figure is actually cropped.

Hover a country to see whether its figure is FAOSTAT-reported or estimated. For estimated countries, the food-energy side is real FAOSTAT data: their own reported crop production, run through the same kcal-per-tonne factors used elsewhere on this page. Only the value side is a World Bank estimate, the same as on the Global Value map above.

Value & Area — Netherlands

Country

Conclusion & Notes

Netherlands

Top Yield Countries (fixed cohort)

2012: 6.5 t/ha → 2022: 8.0 t/ha (+22.8%)

Global Median

2012: 5.2 t/ha → 2022: 5.8 t/ha (+11.2%)

Top producers are pulling further ahead of the global median. This is a fixed historical benchmark. It does not depend on which country currently tops the Top Value chart.

This benchmark stays in tonnage. Unlike most of this page, it does not use dollars. The cohort is defined by tonnage yield, so scoring it in dollars would answer a different question. The Top Value panel above already covers that question. The Global Median side is checked against all 178 countries in this dashboard. About 18% of these have never reported Value of Production to FAOSTAT. Switching this comparator to dollars would shrink it by the same share.

This chart uses crops only, not livestock or rollup categories. Yield equals production divided by harvested area. Cross-crop figures use the median, which is more robust to outlier crops such as greenhouse produce. This chart excludes territories under 1,000 km² and country-years reporting fewer than 5 crops.

Top Crops by Value and Crop Value vs. Cultivated Area, above, undercount the EU after 2017. Eurostat fills in cereals, oilseeds, sugar beet, and tobacco. Fruit, vegetables, wine, and olives are not recoverable at that per-crop level.

Data quality varies by country. FAOSTAT flags each figure as official, estimated, or imputed, but this dashboard does not show that flag. Value per Arable Hectare compares each year's value against one recent arable-land figure, not that year's
